

# Batch Name : OM32

# Module Name : Data Structures

=====

# DS DAY-01:

+ Introduction to an DS:

- if we want to store marks of 100 students

int m1, m2, m3, m4, m5, ....., m100; //sizeof(int)\*100 =  
400 bytes

if we want to sort marks of 100 students =>

int marks[ 100 ]; //sizeof(int)\*100 = 400 bytes

**+ "array" => an array is a basic/linear data structure which is a collection of logically related similar type of elements gets stored into the memory at contiguous locations.**

int arr[ 5 ];

arr : int []  
arr[ 0 ] : int  
arr[ 1 ] : int  
.  
.  
.

primitive data types: char, int, float, double, void

non-primitive data types: array, structure, pointer, enum

- we want to store info of 100 students

rollno : int  
name: char []/string  
marks : float

**+ "structure" => it is a basic/linear data structure, which is a collection of logically related similar and dissimilar type of data elements gets stored into the memory collectively as a single record/entity.**

```
struct student
{
    int rollno;
    char name[ 32 ];
    float marks;
};
```

C => Array

C++ => Array

Java=> Array

Python => Array

=> data structures is a programming concept

=> to learn data structures is not learn any programming language, it is nothing but to learn an algorithm, data structure algorithms can be implemented in any programming language.

=> in this course we will use C programming language.

Prerequisite: C

Q. What is a Program?

Q. What is an algorithm?

Q. What is a Pseudocode?

- to traverse an array => to visit each array element sequentially from first element max till last element.

+ "algorithm" => to do sum of array elements => any human user

step-1: initially take sum var as 0

step-2: traverse an array and add each array element sequentially into the sum variable  
step-3: return final sum

+ "pseudocode" => to do sum of array elements => programmer user

Algorithm ArraySum(A, n){//whereas A is an array of size "n"

```
    sum = 0;
    for( index = 1 ; index <= n ; index++ ){
        sum += A[ index ];
    }
```

```
    return sum;
```

```
}
```

- pseudocode is a special form of an algorithm in which finite set of instructions can be written in human understandable language with some programming constraints.

+ "program" => to do sum of array elements => machine

```
int array_sum(int arr[], int size){
```

```
    int sum = 0;
    int index;
```

```
    for( index = 0 ; index < size ; index++ )
        sum += arr[ index ];
```

```
    return sum;
```

```
}
```

**flowchart => it is a digramatic representation of an algorithm.**

=> an algorithm is a solution of a given problem.

=> an algorithm = solution

- "one problem may has many solutions", and in this case there is a need to decide an efficient solution.

**e.g. searching => to find/search a key element in a given collection/list of data elements.**

1. linear search
2. binary search

**e.g. sorting => to arrange data elements in a collection/list of elements either in an ascending order or in a descending order.**

1. selection sort
  2. bubble sort
  3. insertion sort
  4. quick sort
  5. merge sort
- etc...

- to decide efficiency of an algorithms, we need to do their analysis

- there are two measures of an analysis of an algorithms:

1. time complexity
2. space complexity

**linear search =>**

step-1: accept key from user

step-2:

```
for( index = 1 ; index <= size ; index++ ){  
    //if matches with any array element  
    if( key == arr[ index ] )  
        return true;  
}
```

```
//if key do not matches with any array element  
return false;
```

if key is found in an array at very first pos

if size of an array = 10 => no. of comparisons = 1

if size of an array = 20 => no. of comparisons = 1

if size of an array = 50 => no. of comparisons = 1

.

.  
if size of an array =  $n \Rightarrow$  no. of comparisons = 1  
  
for any input size array no. of comparisons in this case  
= 1  $\Rightarrow$  best case  
running time of an algo in best case =  $O(1)$ .

+ worst case:

if either key is found in an array at last pos or key do  
not found

if size of an array = 10  $\Rightarrow$  no. of comparisons = 10

if size of an array = 20  $\Rightarrow$  no. of comparisons = 20

if size of an array = 50  $\Rightarrow$  no. of comparisons = 50

.  
.

if size of an array =  $n \Rightarrow$  no. of comparisons =  $n$

no. of comparisons = depends on size of an array  
for any input size array no. of comparisons in this case  
=  $n \Rightarrow$  worst case  
running time of an algo in worst case =  $O(n)$ .

+ asymptotic rules: (discrete maths)

"rule-1" : if running time of an algo is having any  
additive/subtractive/divisive/multiplicative constant  
then it can be neglected.

e.g.

$O(n+3) \Rightarrow O(n)$

$O(n-5) \Rightarrow O(n)$

$O(2*n) \Rightarrow O(n)$

$O(n/2) \Rightarrow O(n)$

typedef unsigned long int size\_t;

## 2. binary search:

by means of calculating mid pos big size array gets divided logically into two subarray's => left subarray & right sub array

left subarray => left to mid-1

right subarray => mid+1 to right

for left subarray => value of left remains same, right = mid-1

for right subarray => value of right remains same, left = mid+1

if( left == right ) => subarray contains only 1 ele and it is valid

if( left <= right ) => subarray is valid

in other words :

if( left > right ) => subarray is invalid
